

A total of **five participants** aged between **23 and 26** took part in the usability testing. The participants came from different professional backgrounds, including a software engineer, graduate, journalist, personal trainer, and university student. Overall, the prototype received positive feedback, with ratings ranging from **8 out of 10**, indicating that users recognised the value of the concept while identifying several areas for improvement.

Most participants had a positive first impression of the prototype. They described the interface as clean, visually appealing, and easy to navigate. The concept of helping users discover last-minute local events and discounts was considered useful, particularly for situations where users had no plans, were feeling bored, or wanted spontaneous activities with friends or for dating. Compared with their current approaches, such as asking friends, using Google, ChatGPT, or Ticketmaster, participants appreciated that the prototype provided additional information, including event recommendations, route planning, city busyness, and discounted event opportunities.

Despite these strengths, several common usability issues were identified. The most frequently mentioned problem was **the lack of core functionality**. Users expected features such as ticket booking, payment integration, event prices, live event information, and event search, but found these missing from the current prototype. In addition, multiple participants experienced issues with the **map and location services, including inaccurate positioning, application bugs, and unstable map performance**. Participants also suggested **improving event categorisation and personalisation, as the current recommendations** were considered too broad and not sufficiently relevant to individual interests. Performance issues, including **slow event loading, and the dark colour palette** of the mobile application were also mentioned as factors affecting the user experience.

Overall, participants expressed a willingness to continue using the product, mainly because of the last-minute discounts and the convenience of discovering nearby events. However, they agreed that the prototype requires further development before it can become a fully usable product. Future improvements should focus on completing the **booking process, enhancing map reliability, providing more personalised recommendations, enriching event categories, improving mobile usability, and strengthening the product's unique value proposition**.
